Genetics deals with the molecular structure and function of genes, gene behavior in context of a cell or organism (e.g. dominance and epigenetics), patterns of inheritance from parent to offspring, and gene distribution, variation and change in populations, such as through **Genome-**

Bold

Wide Association Studies. Given that genes are universal to living organisms, genetics can be applied to the study of all living systems, from viruses and bacteria, through plants and domestic animals, to humans (as in medical genetics).

Light Italic

*The fact that living things inherit traits from their parents has been used since **prehistoric times** to improve crop plants and animals through selective breeding.*

Italic

However, the modern science of genetics, which seeks to understand the process of inheritance, only began with the work of **Gregor Mendel** in the mid-19th century. Although he did not know the physical basis for heredity, Mendel observed that organisms inherit traits via discrete units of inheritance, which are now called genes. Genes correspond to regions within DNA, a molecule composed of a chain of four different types of **nucleotides**—the sequence of these nucleotides is the genetic information organisms inherit.
